If you've ever built a plastic model kit, you've seen and know at least something about injection molding. It is a process where heated (molten) plastic is squirted (injected) into a cavity of a designed shape (the mold) and, once cooled, ejected out as a plastic part. Most molds are made of two sides.

10 Simple Design Guidelines One Should Follow in Effective Design of Boss Features in Plastic Parts. Injection molding is one of the most widely used processes for fabrication of plastic parts. The injection molding process requires the injection molding machine, raw plastic, and the mold. The raw plastic is melted in the injection molding machine and then poured into the mold where it is allowed to cool and solidify.

Boss Design Bosses are one of the most common features seen in plastic parts. However, similar to ribs if bosses get too thick relative to the nominal wall thickness, sink can occur. A boss-rib combination can eliminate sink marks.

Consider specifying parallelism instead of flatness. If the plastic part is attached to another (especially a metal part), unrestrained flatness is unimportant. The plastic part will follow the contour. Consider restrained flatness. Again if attached to another component, the plastic part will conform to the contour.

Tips for Machined Plastic Component Design

Designing Your Plastic Part. When designing parts for injection molding, the manufacturing process is an important consideration. Injection molding is a process in which solid thermoplastic resin pellets are melted, injected into a mold, and then cooled back to a solid state in a new form. During both the injection and cooling stages of the manufacturing process, there are several factors that may affect the quality of the final product and the repeatability of the manufacturing process.

Fundamental and common to all plastic part design guidelines is the plea that the designer should maintain a constant wall thickness throughout a plastic part that is to be injection molded. This is considered the “cardinal rule” and is intended to help address mold filling, packing, shrinkage,

residual stress and warpage issues.

An energy director design is used with almost all ultrasonic welding plastic part designs, except when the materials are semi-crystalline. As these have a narrow glass transition temperature range they tend to move quickly into a liquid state rather than the “gummy-ness” typical of amorphous plastics.
